FBX SETTINGS

When you import an oly fbx, you need to change a few parameters:

Go to the Rig tab and set Animation Type to **Generic**. In the Avatar Definition, set it to **Create from this Model.**

If you are importing animations from an existing FBX, set it to Copy from Avatar, and assign the original fbx's avatar. This is useful if your rig setups conflict with each other when exporting animations. You can export different animations in their own fbx and then connect them together with this setting.

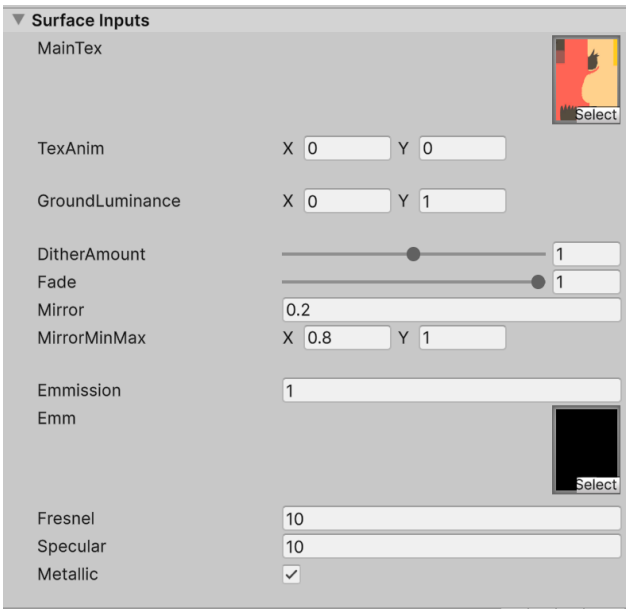

Once you do this, you should be able to see your animations in the Animation tab. Set your idle animation to loop by checking **Loop Time** and check **Loop Pose** and the fbx should be ready to go.

Materials

To create a material, right click on the folder and select **Create > Material**. The project includes the shader the base game uses for its olys. Here's what each parameter does.

- MainTex. The color texture.
- TexAnim. This offsets the texture, you can use this to animate faces.
- GroundLuminance. Offsets the darkening effect on the lower end of the model.
- Mirror. The emission fade in and out speed. MirrorMinMax sets the limits of the effect.
- Emm. The emission texture. Control which parts glow with this texture.
- Fresnel. The rim lighting control.
- Specular. Controls the specular on metallic surfaces.
- Metallic. Controls if the specular is metallic.

To control which parts are metallic, you have to edit the Vertex Color of the model. The **Red** channel controls metallic. Set it to 0 to remove metalness.

CREATING AN OLY

This guide will help you setup 3D olys. We'll use Blender to for this guide. This is not a Blender tutorial.

Video: https://youtu.be/IeH0-k1WM0E

Preparations

Open the Olympus Modding Tools Unity project. On the Assets folder, create a new folder with the name of your mod.

Within that new folder, create another folder called Oly. This where you will hold all your olys. You may create a subfolder for each one if you need to.

Go back to the mod folder and right click. Hit **Create > SteamItem > SteamworksItem**

Step 1.

Once you have your 3d model textured and rigged, make sure you create at minimum the following animations:

- idle
- damage
- death
- phys
- wave
- beam

Make sure you name them all in lower caps. You don't need both wave and beam animations.

Step 2.

Modify the rig by adding the following bones:

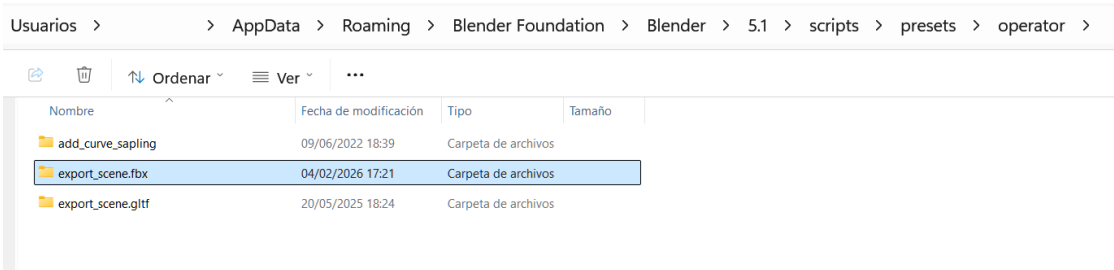

- b_cam
- b_damage
- b_wave
- b_beam

These bones are used to position attack vfx or as a target for the camera.

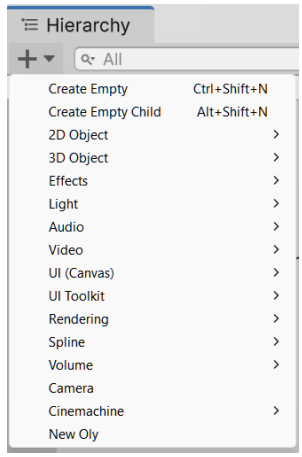

Step 3.

Export the model in FBX format using the OlympusFBX preset. You can find it in the Olympus

Modding Tools. In order to see the preset, copy and paste the python script into this folder (use the folder of the Blender version you're using). After that, close and open Blender and it should show

up as an option in the FBX exporter presets.

Step 4.

In Unity, position your mouse on the Hierarchy and right click. At the bottom of the context menu, click New Oly.

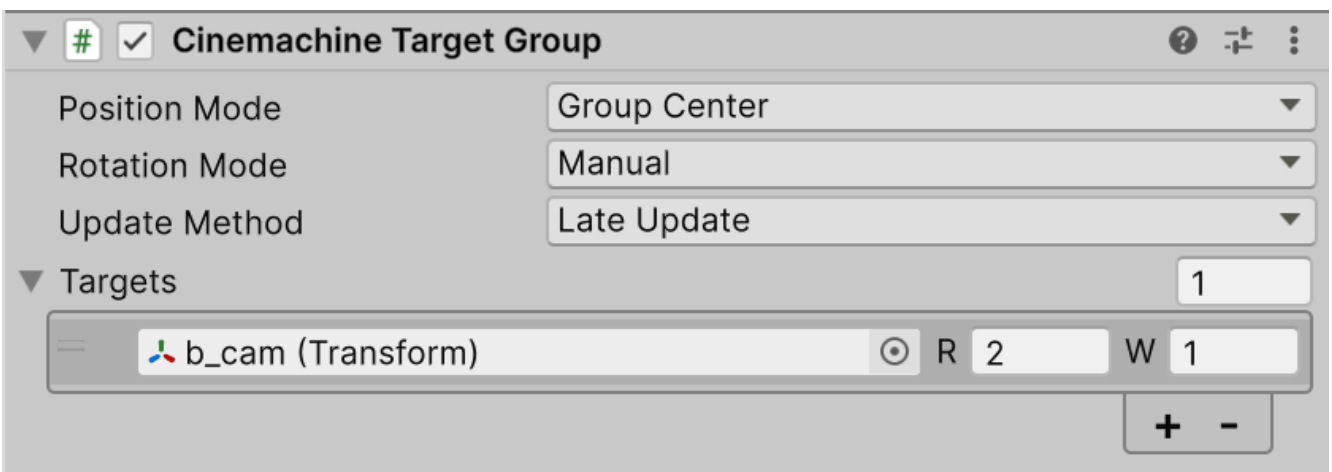

Step 5

Drop your fbx file on the created object.

Step 6

Select the target Object. In the Inspector, assign the b_cam bone to the Target Group component.

Step 7

Assign your b_beam bones to the MData component in the created object.

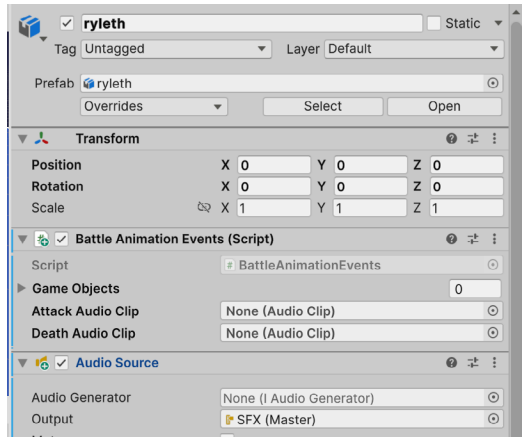

Step 8

Name the created object the name of your oly.

Step 9

Select the fbx object in the hierarchy and add the Battle Animation Events component and AudioSource component.

Step 9

On the project folder, create an oly data file. Right click, **Create > Oly > Oly**

Name it the same as your oly prefab, otherwise the game won't be able to load the model even if it imported correctly.

Step 10

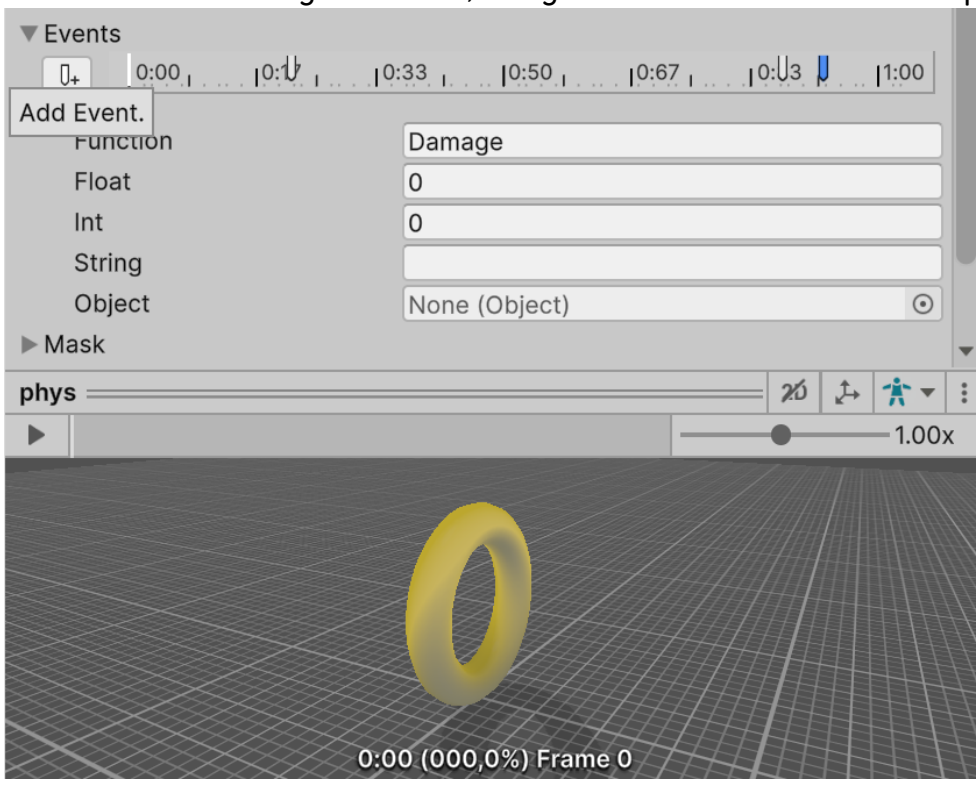

Drop your oly object into the Oly folder of your mod. This creates a prefab, which is basically saving the object to disk.

Step 11

Now we have to set up the animation events. These events will trigger your moves' vfx or straight up trigger the damage on the target.

There are cosmetics events like **CryAttack** and **ToggleObjects**

For the phys animation, you will need to add the event **Damage**. Just click the Add Event button and move the event to where the animation should trigger the damage animation on the target. This could be at the end of a tackling animation, or right when a kick animation swipes, etc.

For the wave and beam animations, you need to add **SpawnFX** instead. To learn more about the differences between these two events, check the **Creating a move** section.

For the “death” animation, you need to add the **DieEffect** event. This makes the oly start shining and disappear when it fades. Move the event to somewhat close to the end of the animation.

To make the oly make a sound when entering into battle or fading, add **CryEnter** and **CryDeath** events.

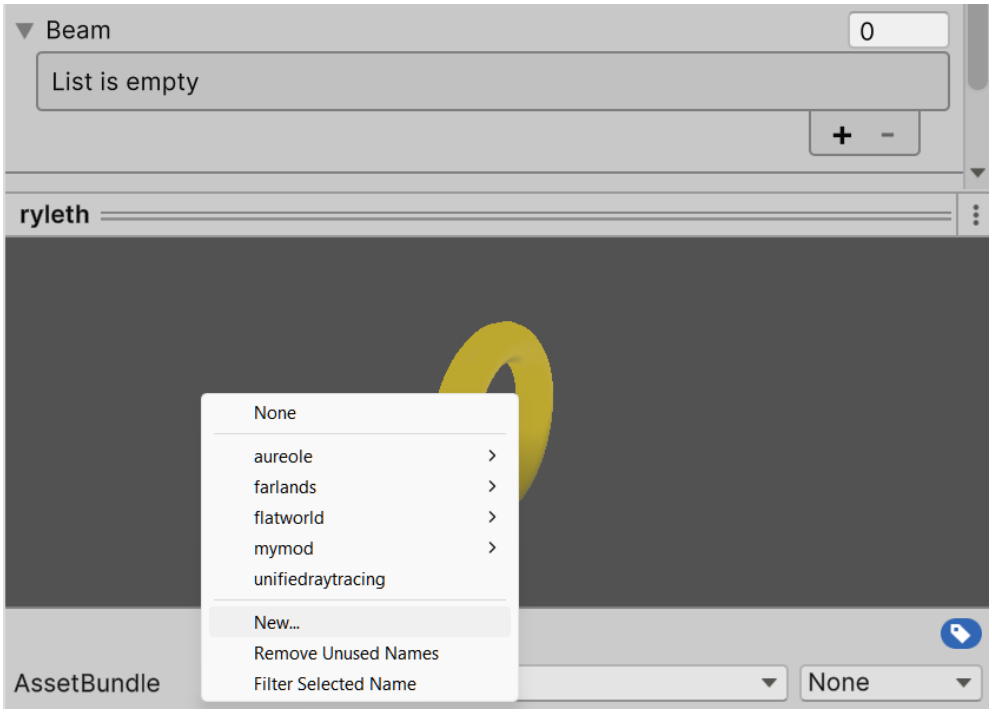

ToggleObjects

The ToggleObjects event takes an int parameter. Looking back at the prefab you created, in the BattleAnimationEvents, you can see a Game Objects list. This list takes unity objects that can be toggled on with this animation event. To select which object to toggle, set the Int parameter to the index of the object in the list. You can check the ryleth oly in the Aureole mod for reference.

Step 12

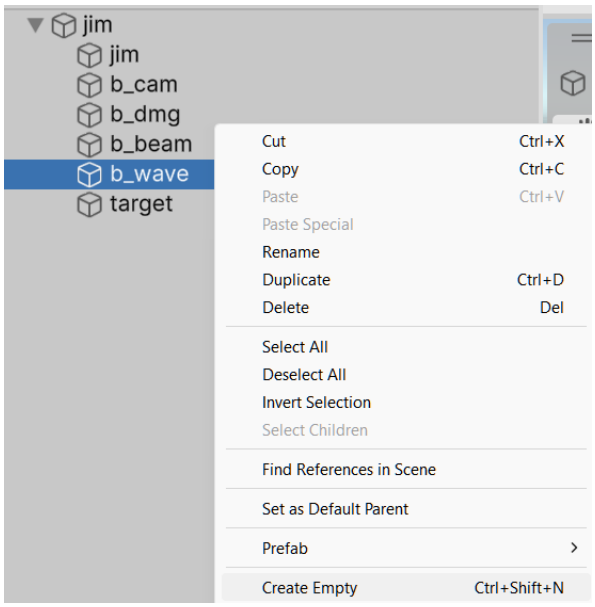

Now that you have your oly object ready, select your oly prefab and click on the bottom right to open the AssetBundle tab.

Click on the AssetBundle and add a new bundle path. You have to name it **modname/oly/oly**

CREATING A 2D OLY

Follow the steps of Creating an Oly from Step 4 to Step 9. Instead of using bones, create New Gameobjects within the created object.

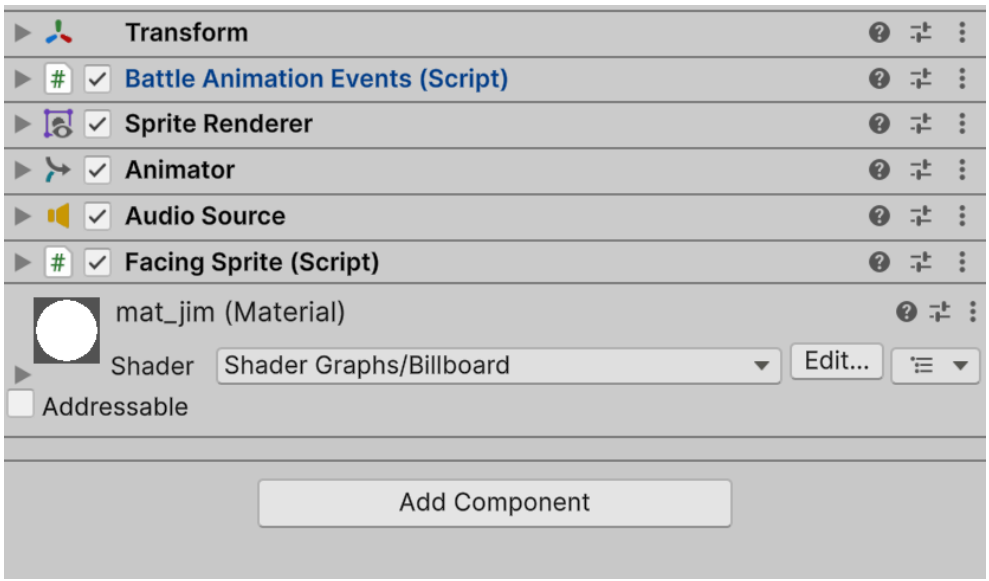

You will also need to create a new GameObject instead of dropping an FBX file. assign the BattleAnimationEvents component and AudioSource as usual and add an Animator component too.

These are all the components that the 2d object needs.

The Sprite Renderer needs the BillBoard material so it always faces the camera.

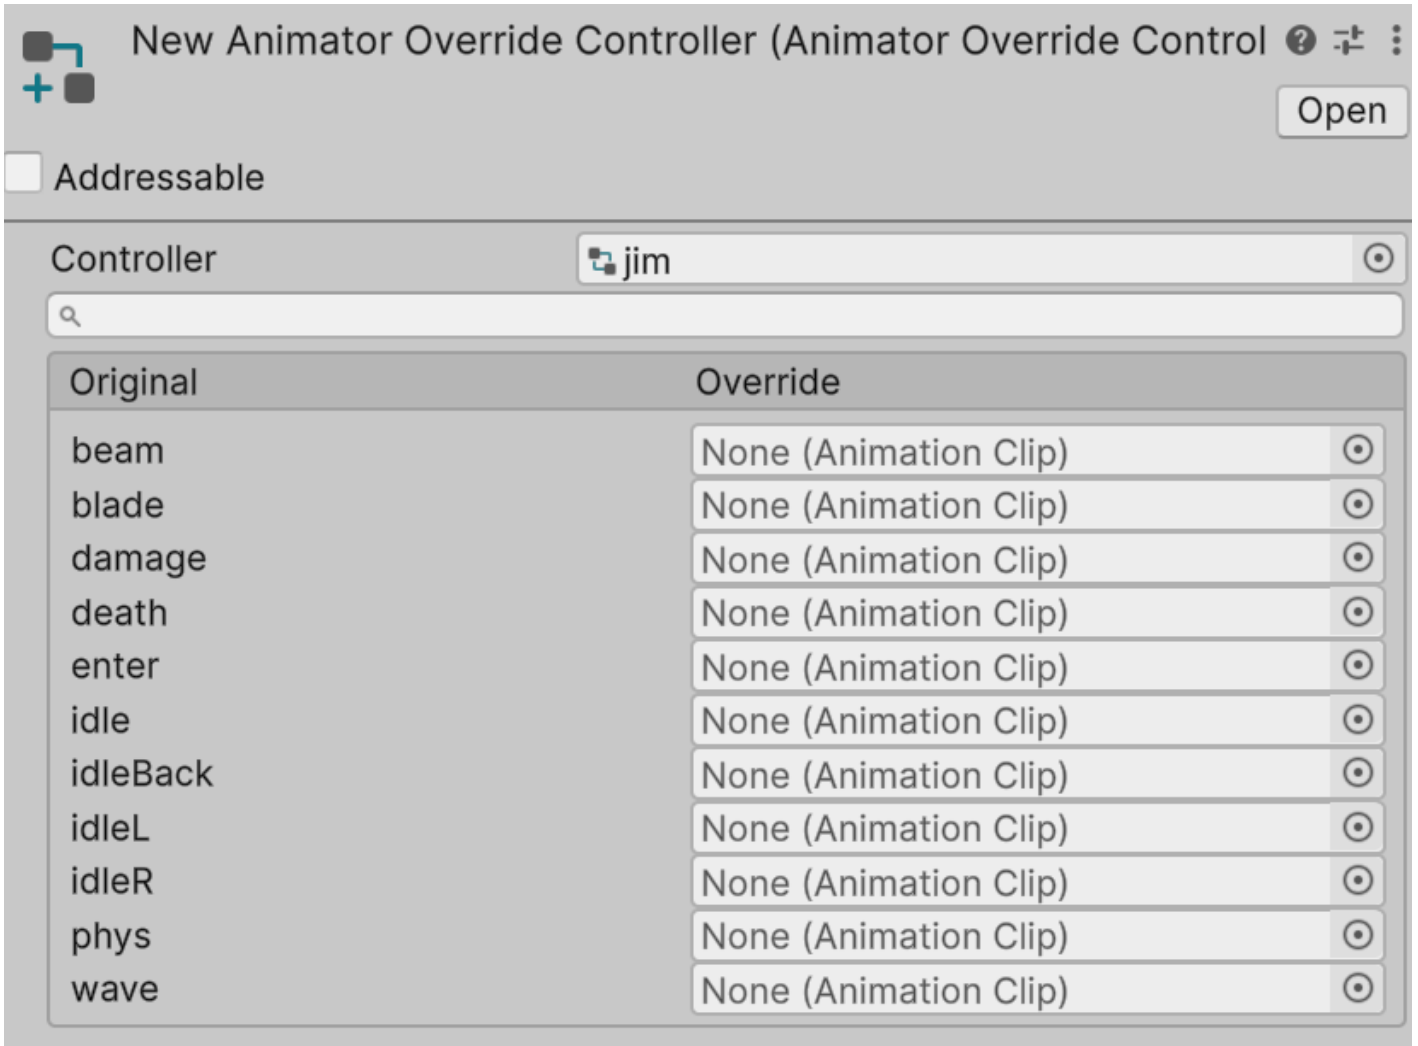

The Facing Sprite component gives animator data so the animator can handle which animation direction to

display.

You also need to create an Animation Controller to assign to the Animator component. In the Oly folder, right click and **Create > Animation > Animator Override Controller**.

Assign Jim's animator to the source and override the animation clips with yours. If Jim's animations aren't enough, you can delete the override and just copy Jim's animator and expand it yourself.

New Animator Override Controller (Animator Override Control
Open

idle
None (Animation Clip)
idleBack
None (Animation Clip)
idleL
None (Animation Clip)
idleR
None (Animation Clip)
phys
None (Animation Clip)
wave
None (Animation Clip)

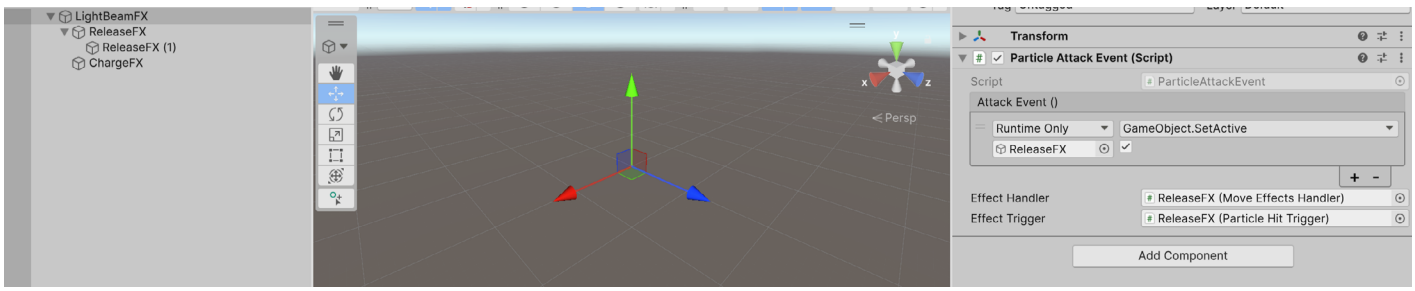

CREATING A MOVE

Step 1

Create your move's vfx in unity. you may use vfx graph or particle system. you need a particle system for spawnfx events.

Step 2

If the move uses SpawnFX events. Create a parent empty to your vfx. Add **ParticleAttackEvent** component to the parent. If the move uses a SpawnFX animation event, the Objects that you add

to the Attack Event list will be toggled on when the animation event fires. Check LightBeamFX for reference.

The effects handler component helps position and aim the vfx at the target. You may also add SetPosition components to override the position of your VFX.

Step 3

Add ParticleHitTrigger to the vfx that will fire on **SpawnFX**. Set Callback Type to OnDelay and set how long it will take to damage the target after this vfx fires (usually 1-2s is enough).

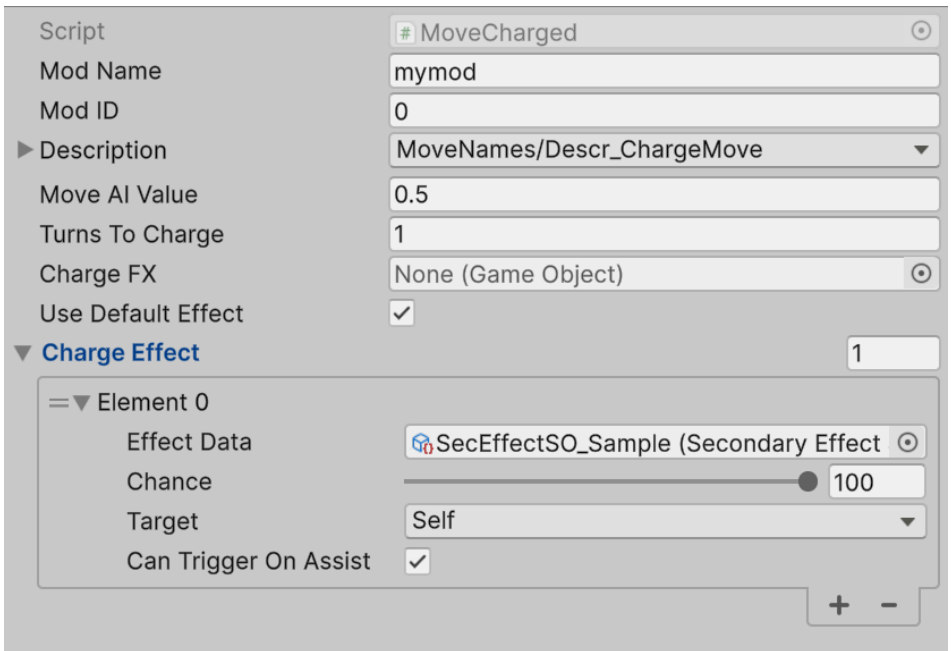

If you're using **Damage** animation event you don't need this. The animation event will trigger the damage instead of the move vfx.

MOVE INTERACTORS

To create move interactor, right click on the project folder and click **Create > Oly > Moves > MoveEffectors.** Every Effector includes an AI weight, use it to make the AI more likely to select this move.

MoveCharged

This interactor adds charging turns to a move. Set how many turns you want to wait before the move fires. You can add secondary effects to trigger on each charging turn. Check **Use Default Effect** if you don't need to use your own VFX for charging. Remember to add your vfx to the move asset bundle if you make one. The sample included in the project holds the default description for the effect.

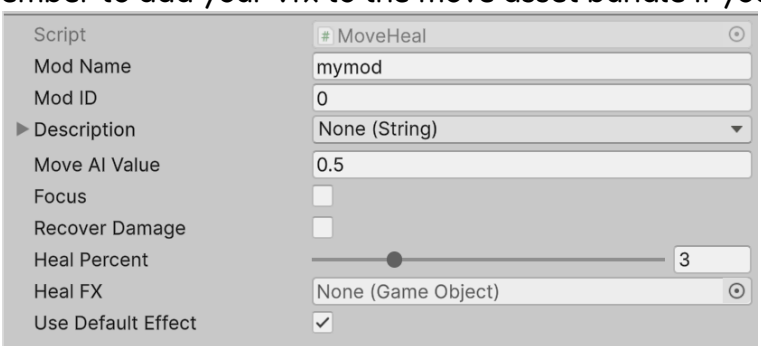

MoveProtect

This effector makes you immune to any move. The sample included in the project holds the default description for the effect.

MoveHeal

This interactor heals your oly. It can either heal by sapping hp from the target or just by itself. Set Recover Damage to make it sap HP. Check **Use Default Effect** if you don't need to use your own VFX for charging. Remember to add your vfx to the move asset bundle if you make one.

MoveBeforeSwitch

This move triggers early if the target is about to switch. Otherwise it triggers at the usual pace.

MoveSwitch

Set Self to true to make the user switch out after the attack. Leave it false to make the target switch out. If you leave Random to off the affected oly will manually select the oly to send.
